WHY ZERO-VOLTAGE SWITCHING When a MOSFET turns on, there are losses due to voltage and current overlap (Figure 3) and the discharge of stored energy in its Coss capacitor. In ZVS the Coss is tricked into discharging its energy prior to turning on the MOSFET. Usually the MOSFET's body diode goes into conduction in the process.

A. Full Load Failure Mode Some MOSFET failure modes are inherent to the full-bridge ZVS converter. The power MOSFET is turned on at zero voltage because its body diode needs to conduct first and clamps the drain-source to 0.7V in the phase-shifted ZVS full-bridge topology. No dynamic voltage stress is imposed on the drain of

Abstract: Phase-shifted zero-voltage-switching (ZVS) full bridge topologies are gaining popularity due to their extremely low switching losses in the power devices even at higher switching frequency. However the intrinsic body diode is required to conduct in order to create the ZVS turn-on rendition for the power MOSFET.

the MOSFETs to achieve zero voltage switching (ZVS). When the PWM pulse is off, the snubber inductance L_r , by way of storage energy, will resonate with the output capacitances of the MOSFETs and oscillate the MOSFET voltage to zero before the MOSFETs turn on at the next period. At this stage, ZVS (which means no switching loss)

This is mainly due to switching losses within the regulator MOSFETs. These must be overcome or avoided to achieve any significant boost to regulator performance. A better solution uses Zero Voltage Switching (ZVS) topology, which allows for operation at a higher frequency and at higher input voltages without sacrificing efficiency.

The basic idea of zero voltage switching is simple. Prior to turn on, the MOSFET V_{DS} is at a high voltage, which is also the voltage to which C_{OSS} is charged. To achieve ZVS, the C_{OSS} is tricked into discharging its energy before the gate signal is applied. Even a partial discharge is beneficial though ideally, all of the energy stored in C_{OSS}

The voltage across Gate and Source i.e. VGS is made appropriately positive (technically speaking, $V_{GS} > V_{TH}$), the MOSFET enters linear region and the switch is ON. This makes the Light to turn ON. If the input Gate voltage is 0V (or technically $< V_{TH}$), the MOSFET enters cut-off state and turns off. This in turn will make the light to turn OFF.

the source voltage, i.e., $v_2 = V_{DC}$, and switch S 1 turns on at zero voltage. As a result of the transition, the charge Q_{oss} was moved from switch S 1 to the dc source and the energy of the inductor L_{σ} is zero whereas the total energy stored in the MOSFET bridge leg remains unchanged. Thus, the condition for complete soft switching equals $1/2 LI$
