The ciliates are a group of protozoans characterized by the presence of hair-like organelles called cilia, which are identical in structure to eukaryotic flagella, but are in general shorter and present in much larger numbers, with a different undulating pattern than flagella. Cilia occur in all members of the group and are variously used in swimming, crawling, attachment, feeding, and sensation. Ciliates are an important group of protists, common almost anywhere there is water — in lakes ...

Essentially, ciliates are ciliated protozoans. As such, they are protists that belong to the super-group known as Alveolataalong with dinoflagellates and apicomplexans. Because they are larger cellscompared to other single-celled organisms, they feed on a number of othermicro-organisms including bacteria and algae.

Hypothetical evolution of ciliated protozoa based on both morphological and molecular data to show the relationship and the positions of the taxa at order level. The subphylum Postciliodesmatophora comprises two classes, the Heterotrichea and Karyorelictea, both of which were recovered as monophyletic groups in our analyses.
